Chapter 1

Introduction

Chapter 2

Theory

We consider a system of electrons situated in an isotropic harmonic oscillator potential. We will use Hartree's atomic units¹ in order to get the idealized Hamiltonian presented below:

$$H = \sum_{i=1}^N \left(-\frac{1}{2} \nabla_i^2 + \frac{1}{2} \omega^2 |\mathbf{r}_i|^2 \right) + \sum_{i<j} \frac{1}{r_{ij}}. \quad (2.1)$$

Here $r_{ij} = |\mathbf{r}_i - \mathbf{r}_j|$ is the distance between two electrons. The first sum is the single particle harmonic oscillator potential. Because electrons repel each other, we also get the latter repulsive sum as part of the Hamiltonian - the perturbation of the system.

2.1 The unperturbed wave function

Disregarding interactions, there is a closed-form solution for the Hamiltonian shown in equation (2.1) for a single particle. The solution follows (Hjorth-Jensen, 2021):

$$\phi_{n_x, n_y}(x, y) = A H_{n_x}(\sqrt{\omega}x) H_{n_y}(\sqrt{\omega}y) \exp \left[-\frac{\omega}{2} (x^2 + y^2) \right].$$

Here, H_i are Hermite polynomials (see A.1), and A is the normalization constant. For the lowest lying state, we have $n_x = n_y = 0$ and hence the energy of a non-interacting fermion ϵ is:

$$\epsilon_{n_x, n_y} = \omega(n_x + n_y + 1) = \omega. \quad (2.2)$$

¹ $\hbar = c = e = m_e = 1$, see Hartree (1928).

The Pauli exclusion principle states that two fermions can not occupy the same quantum state simultaneously. For each state (n_x, n_y) a fermion may have spin up or down, which means it can be occupied by at most two fermions. Using this principle, the ground state energies of the closed shell configurations $N = 2, 6, 12$ and 20 can easily be calculated using equation (2.2). The energies are given in table 1.

Table 2.1: The ground state energy of N non-interacting particles in an isotropic harmonic potential well. ω is the oscillator frequency. Energies are given in Hartree’s atomic units.

| Number of particles N | E (a.u) |
|-------------------------|------------|
| 2 | 2ω |
| 6 | 10ω |
| 12 | 28ω |
| 20 | 60ω |

These energies serve as great values to benchmark our program against.

2.2 The complete wave function

Single harmonic oscillators are solvable analytically, but introducing the repulsive perturbation forces us to tackle the problem differently. We choose a variational Monte Carlo approach, and use the Slater-Jastrow type of trial wave function, namely

$$\Psi_T(\mathbf{R}, \alpha, \beta) = \Psi_D \Psi_J = \det(D(\mathbf{R}, \alpha)) \exp(J(\mathbf{R}, \beta)),$$

where $D(\mathbf{R})$ is a Slater matrix and $J(\mathbf{R})$ is a Padé-Jastrow correlation function. \mathbf{R} here represents the set of all the individual particle’s positions, and α and β are the variational parameters. Following Hjorth-Jensen (2021), our ansatz for the factors of this trial wave function is:

$$\Psi_D = \det(D(\mathbf{R})), \quad D_{ij} = \phi_j(\mathbf{r}_i),$$

$$\Psi_J = \prod_{i < j}^N \exp\left(\frac{ar_{ij}}{1 + \beta r_{ij}}\right).$$

$\phi_j(\mathbf{r}_i)$ is the single particle wave function for the i -th fermion, as described in 2.1, with j being an index describing each unique quantum state². The coefficient $a = 1$ when the electrons i and j have anti-parallel spins, and $a = \frac{1}{3}$ when their spins are parallel. The index notation on the product is as explained in A.2.

²E.g. $(0, 0, \uparrow)$, $(2, 1, \downarrow)$, etc.

2.2.1 A system of $N = 2$ fermions

The total wave function for a non-interacting two-electron system is given as:

$$\Phi(\mathbf{r}_1, \mathbf{r}_2) = C \exp \left[-\frac{\omega}{2} (|\mathbf{r}_1|^2 + |\mathbf{r}_2|^2) \right],$$

with an energy of 2ω . The total spin in the ground state is simply zero as the two electrons living in the state is paired with opposite spins (eg. $\pm 1/2$).

The ground state energy is given by the unperturbed system. Adding a perturbation/interaction will rise the energy. For the simplest system with two electrons, this perturbation can be found through perturbation theory, whilst for a higher number of particles, other measurements or actions must be taken to find the energy(?).

2.3 Local energy

By definition, the local energy is given by

$$E_l = \frac{1}{\Psi_T} \hat{H} \Psi_T$$

Ψ_T is the trial wavefunction of the system. The Hamiltonian is given by equation (2.1) and the trial wavefunction is

$$\Psi_T(\mathbf{r}_1, \mathbf{r}_2) = \Psi_1 * \Psi_2 = C \exp(-\alpha\omega(r_1^2 + r_2^2)/2) \exp\left(\frac{ar_{12}}{1 + \beta r_{12}}\right)$$

Where $a = 1$ when the two electrons in question have anti-parallel spins and $a = 1/3$ when the spins are parallel. α, β are the variational parameters.

Hence, the local energy is shown to be (see appendix)

$$E_L = 2\alpha\omega + \frac{1}{2} + \omega^2(1 - \alpha^2)(r_1^2 + r_2^2) - \frac{a}{(1 + \beta r_{12})^2} \left(-\alpha\omega r_{12} + \frac{a}{(1 + \beta r_{12})^2} + \frac{1 - \beta r_{12}}{r_{12}(1 + \beta r_{12})} \right) + \frac{1}{r_{12}}. \quad (2.3)$$

Equation (2.3) is our analytic expression for the local energy of the two electron system.

The numerical local (kinetic) energy is calculated using the derivative of the velocity utilizing the two point approximation of the first derivative

$$\frac{dg(x)}{dx} \approx \frac{g(x + \Delta x) - g(x - \Delta x)}{2\Delta x}$$

Second derivative by three point approximation

$$\frac{d^2g(x)}{dx^2} \approx \frac{g(x + \Delta x) - 2g(x) + g(x - \Delta x)}{\Delta x^2}$$

Δx is the stepsize which we let run towards zero. The error is proportional to (Δx^2) .

Chapter 3

Method

3.1 Testing

Testing in Rust is normally divided in two categories: *unit tests* and *integration tests*. Unit tests are small codes to test specific functions inside the code. These tests are normally written in the same file as the functions themselves, but inside a module annotated with `cfg(test)`.

On the other hand, integration tests are written externally to the library, and is made to test the integration of the functions in the program. These tests are often much larger than unit tests, and are made to make sure that the internal functions work well with each other, from the standpoint of an external user. Therefore, integration tests are normally written in a separate `tests` directory at the same level as the `src` directory.

We will write mainly unit tests in our program, to ensure that our functions return the expected values, and to reduce the mental overhead of debugging when making larger changes to the codebase.

More on testing can be found in the official documentation of the Rust programming language (Rust-Docs, 2021).

Discussion

Chapter 6

Conclusion

Appendix A

Appendix

A.1 Hermite polynomials

The Hermite polynomials are the solutions to the following contour integral (Arfken & Weber, 2005):

$$H_n(z) = \frac{n!}{2\pi i} \oint e^{-t^2 - tz} t^{-n-1} dt.$$

In this report, we will consider the real Hermite polynomials, and only up to a given order. A computationally efficient way of finding these is given by the following sequence:

$$H_n(x) = c_{n+m}x^n + c_{n-1+m}x^{n-1} \dots + c_mx^0, \quad m = \sum_{i=1}^n i$$

where the coefficients c_n are given by the triangle sequence shown in (A.1).

$$c_i = 1, 0, 2, -2, 0, 4, 0, -12, 0, 8, 12, 0, -48, \dots \quad (\text{A.1})$$

This is just a selection of the sequence, the rest is fetched from the work by Jovovic (2001).

A.2 Index notation for sums and products

For products and sums, the following convention is used:

$$\sum_{i < j}^N = \sum_{i=1}^N \sum_{j=i+1}^N, \quad \text{or} \quad \prod_{i < j}^N = \prod_{i=1}^N \prod_{j=i+1}^N$$

A.3 Analytical Laplace of the Trial wavefunction

The trial wavefunction of a two-particle system is

$$\Psi_T(\mathbf{r}_1, \mathbf{r}_2) = \Psi_1 * \Psi_2 = C \exp(-\alpha\omega(r_1^2 + r_2^2)/2) \exp\left(\frac{ar_{12}}{1 + \beta r_{12}}\right)$$

as defined in theory section 2.3.

The Laplacian is the double derivative in all dimensions, defined as:

$$\Delta f = \frac{\partial^2 f}{\partial x^2} + \frac{\partial^2 f}{\partial y^2} + \frac{\partial^2 f}{\partial z^2}$$

The calculations:

Calculate all the shit
